

Cosmic Reionization & High-redshift Galaxies

宇宙再电离和高红移星系

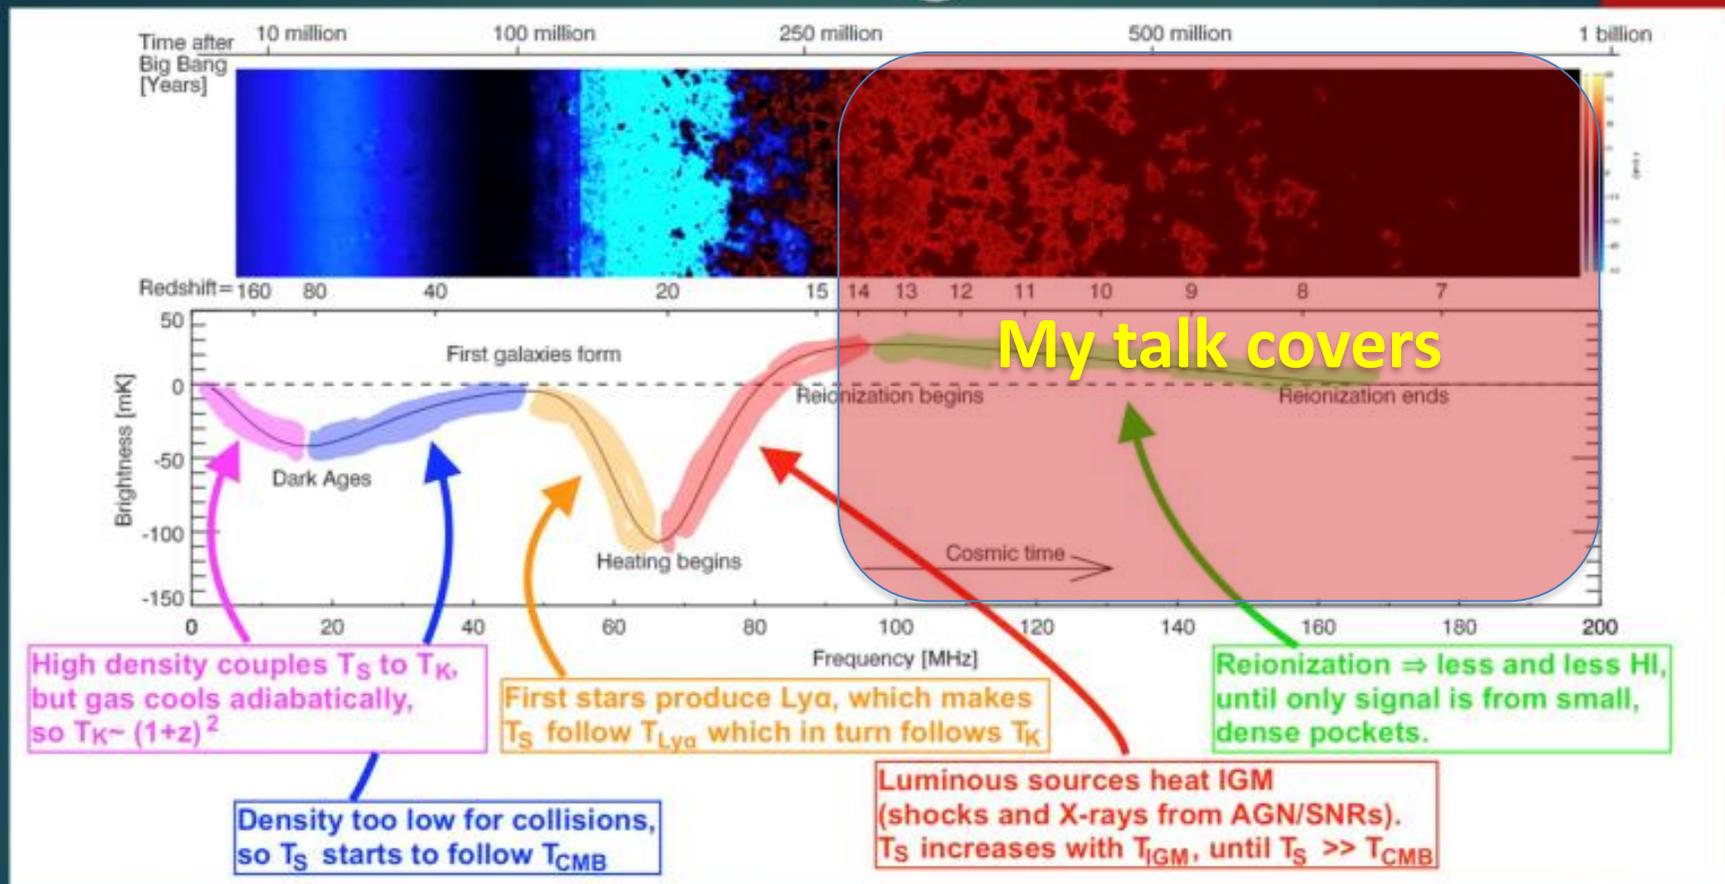

Zhen-Ya Zheng (郑振亚)

Shanghai Astronomical Observatory, CAS

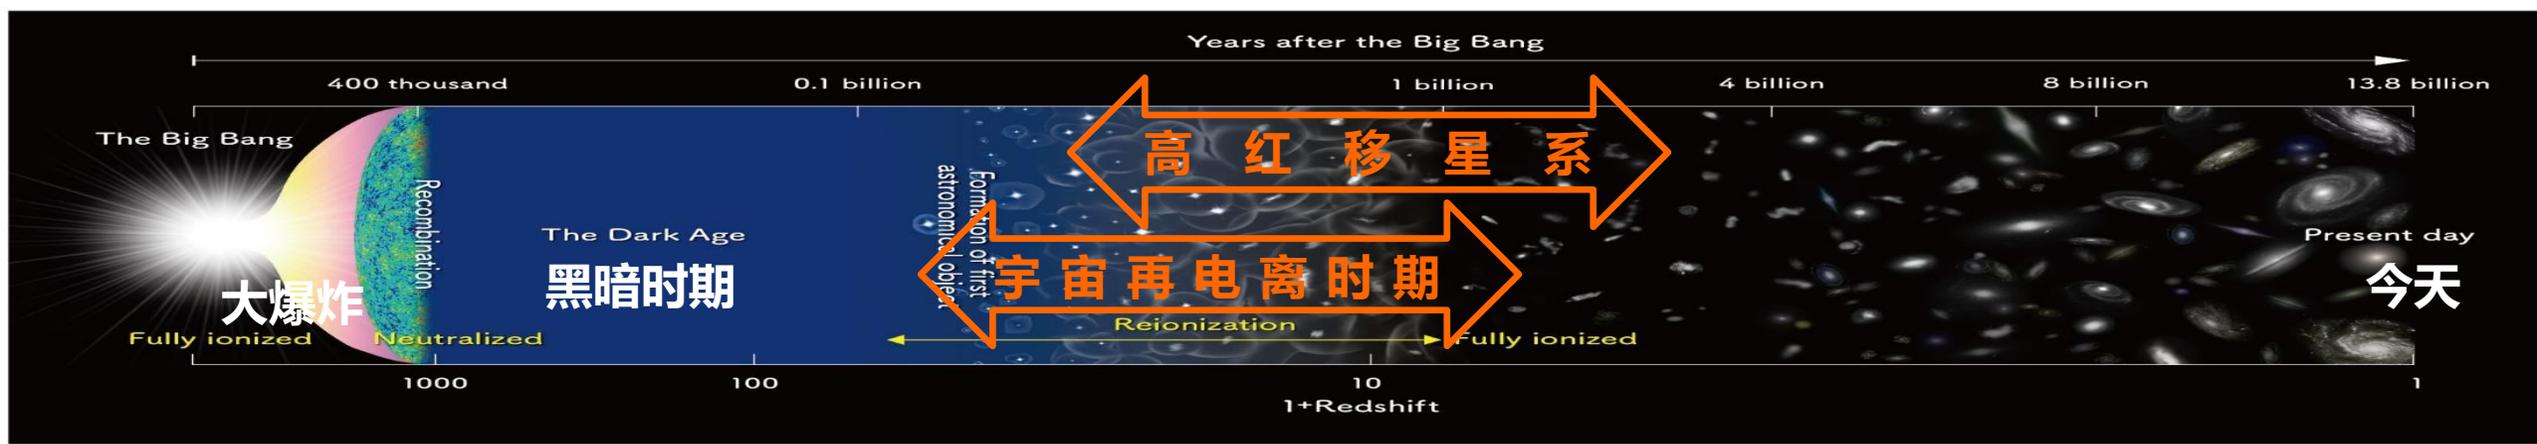

The Summer School for 21cm Cosmology

Global 21 cm signature

- $200 < z < 1100$: $T_s = T_{CMB}$, no 21 cm signals
- $40 < z < 200$: $T_s \sim T_k$, $T_k \sim (1+z)^2$, $T_b < 0$
- $z_* < z < 40$: collisional coupling ineffective and radiative coupling to the CMB sets $T_s = T_{cmb}$, no 21 cm signals

Why study cosmic reionization?

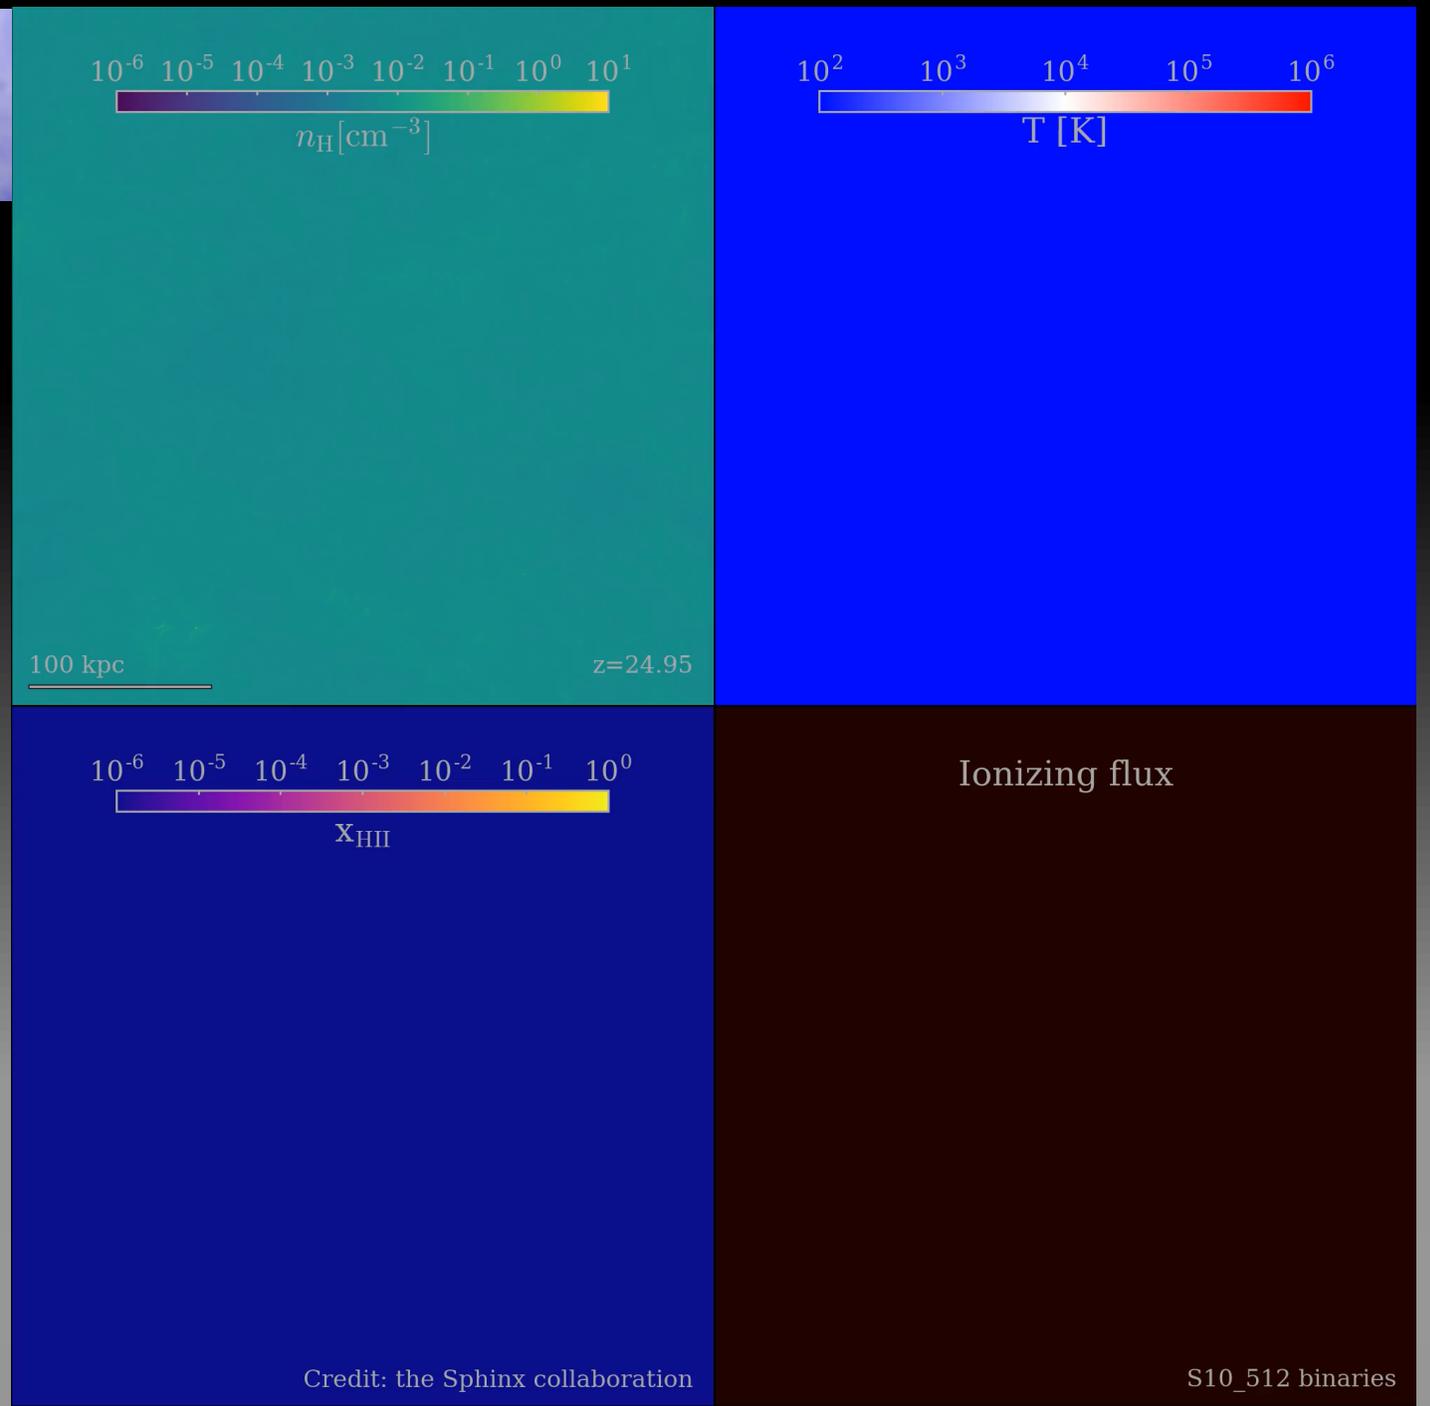

- ◆ Cosmic reionization is the **last major phase transition** of most baryonic matter in the Universe. It involves the conversion of cold, neutral hydrogen into highly ionized hydrogen in the intergalactic medium, implying the **end of the Dark Age** and the **beginning of the Age of Galaxies**.
- ◆ This process reflects the formation, radiation, and dynamical characteristics of **first-generation objects**, small-scale **density fluctuations**, cosmic **chemical evolution**, **early stellar formation and black hole accretion** histories, and a complex series of **feedback** mechanisms.

How do we search for high-z objects?

- Lyman Break Galaxies (LBGs)

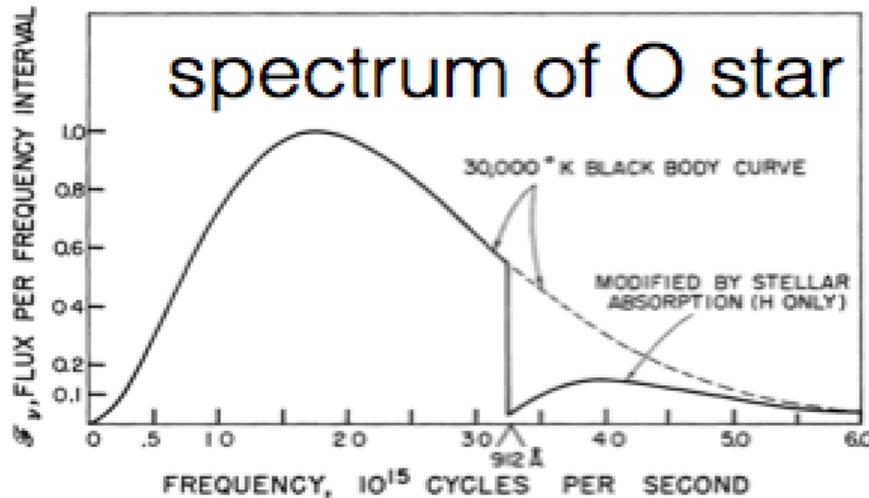

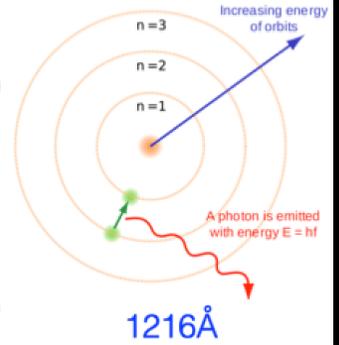

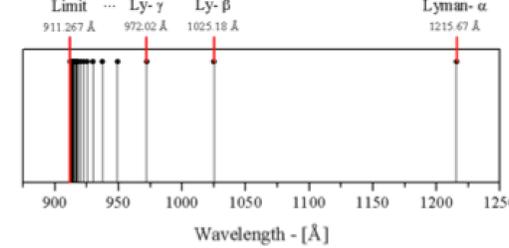

How do we search for high-z objects

- **Lyman-alpha Emitters (LAEs)**

1 H Hydrogen	2 He Helium
3 Li Lithium	4 Be Beryllium

Elements after big bang

Hydrogen in our Universe:
~73%(mass); >90%(number)

UV photons radiative-transferred by neutral hydrogen

$N(\text{Ly-a})/N(\text{UV}) \sim 68\%$

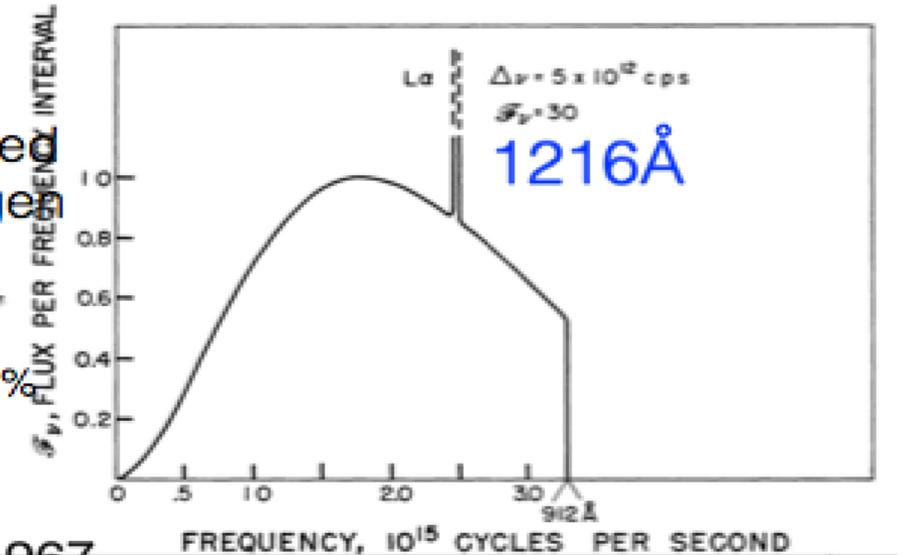

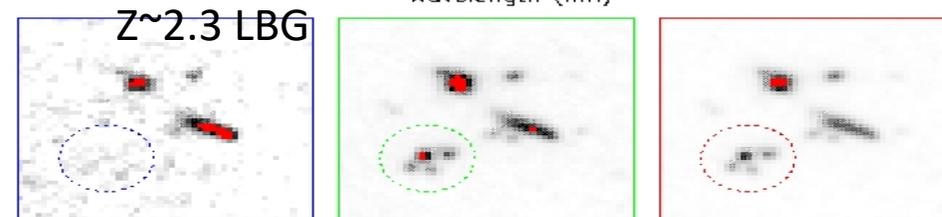

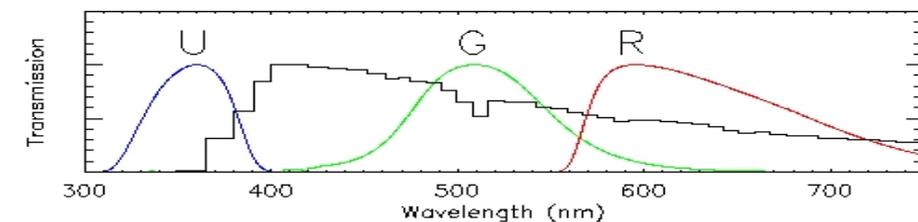

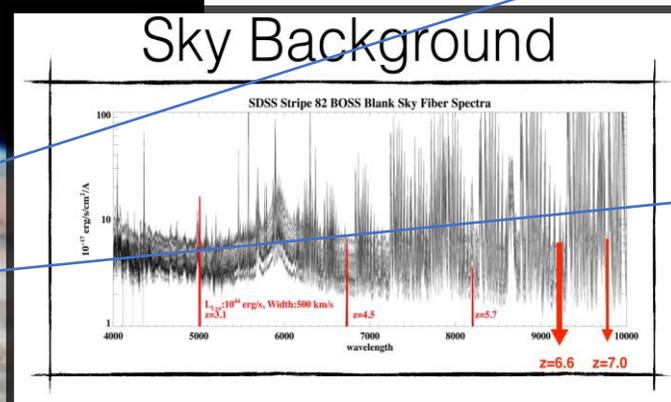

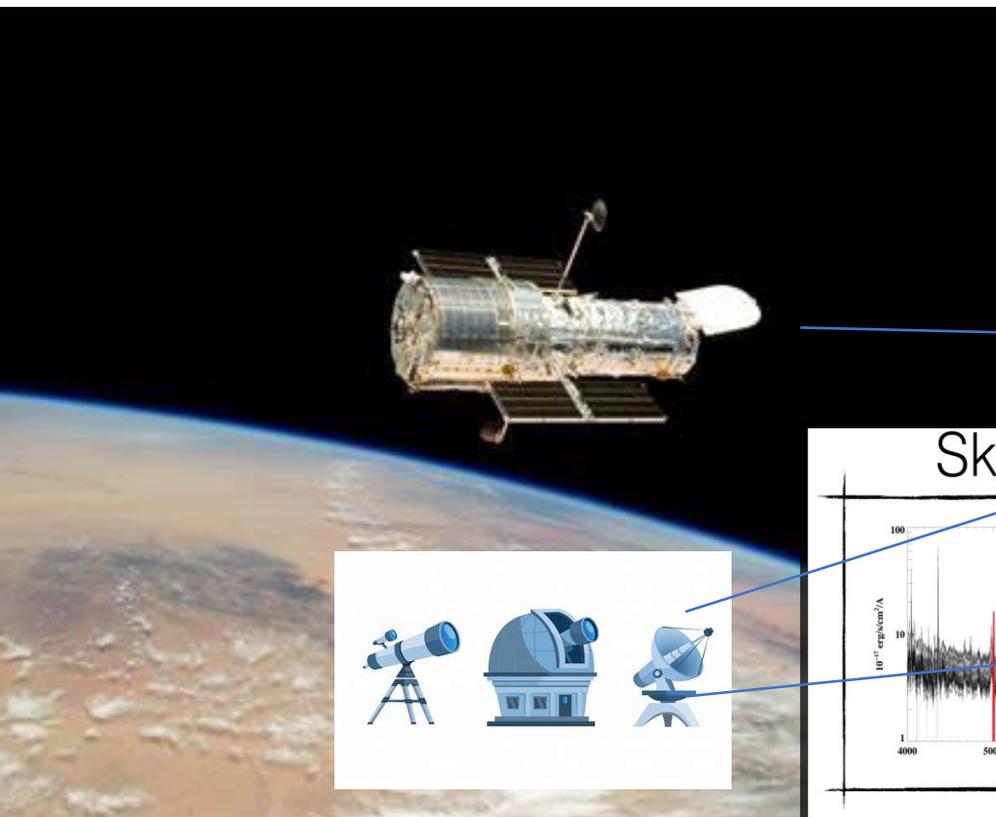

FIG. 2.—The spectrum is a black-body spectrum calculated for $T_e = 30000^\circ \text{K}$ (the assumed effective temperature of the star).

Partridge & Peebles 1967

- Primeval galaxies (at very high-z) are composed of newly formed massive stars.
- The ionizing UV photons generated by massive stars are transferred into strong Lyman- α emission lines with hydrogen atoms in the interstellar medium.
- These galaxies are known as Lyman- α emitter galaxies (LAEs).

Searching Methods for High-z Galaxies

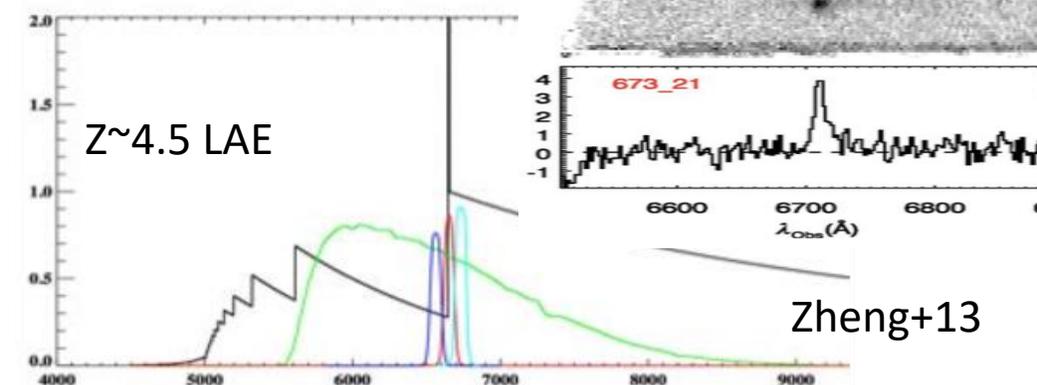

Lyman-Break Galaxies (LBGs)

Spectral break around (rest-frame) 912Å by absorption of neutral H

Lyman-α Emitter Galaxies (LAEs)

Spectral line around (rest-frame) 1216Å by resonant scattering of neutral H

Ionizing Budget

Exploring Reionization Contributors

Reionization Equation
(Madau+99)

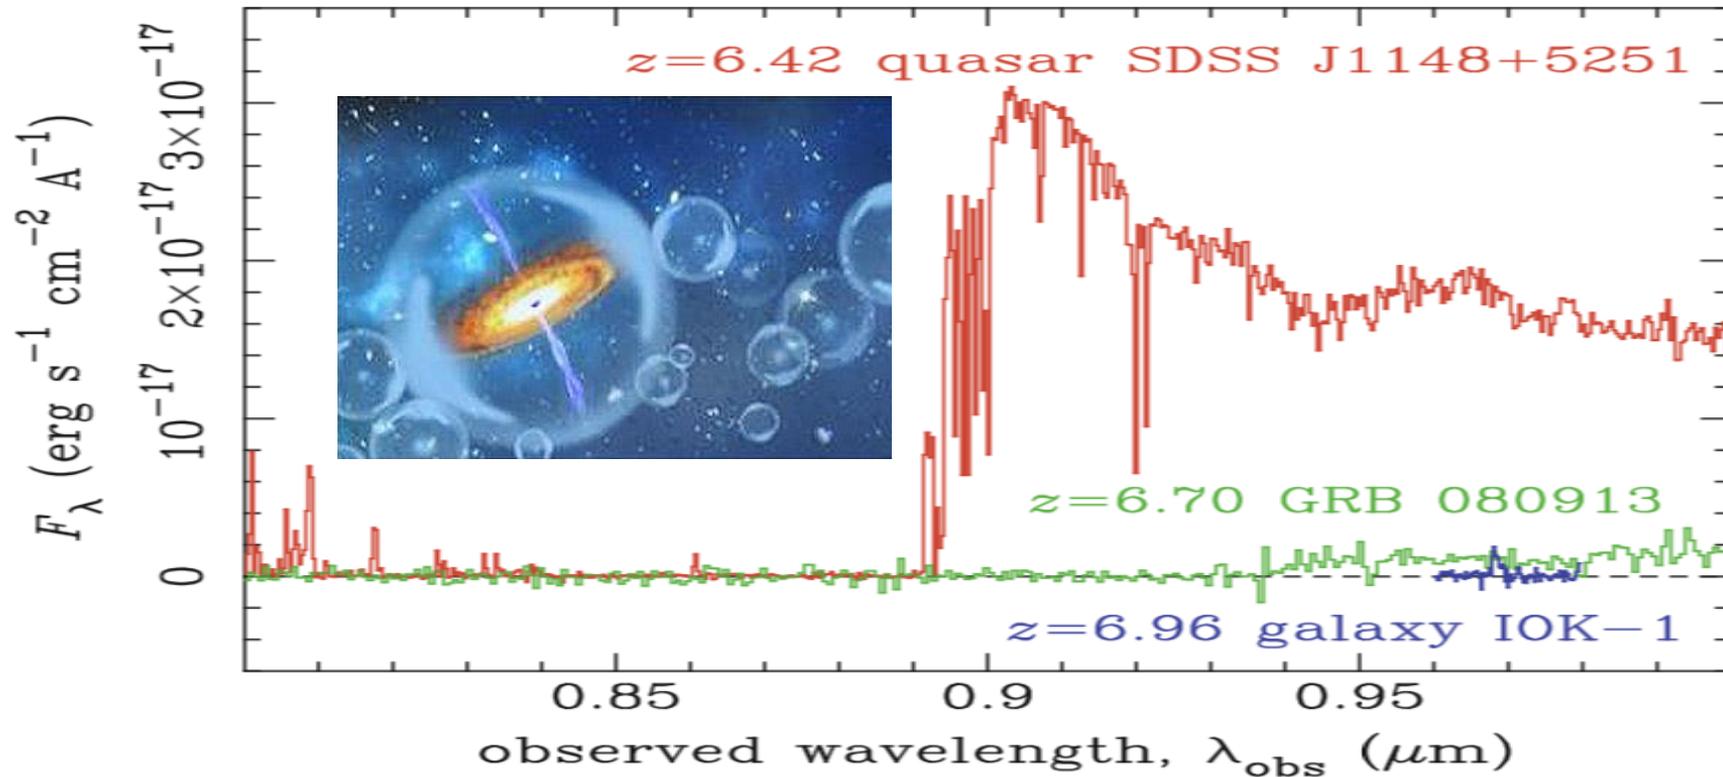

$$\frac{dQ_{\text{HII}}}{dt} = \dot{n}_{\text{ion}} - \frac{Q_{\text{HII}}}{\bar{t}_{\text{rec}}},$$

Production rate of ionization photons:

$$\dot{n}_{\text{ion}}^{\text{com}} = \int_{M_{\text{lim}}}^{\infty} dM_{\text{UV}} \phi(M_{\text{UV}}) \gamma_{\text{ion}}(M_{\text{UV}}) f_{\text{esc}}.$$

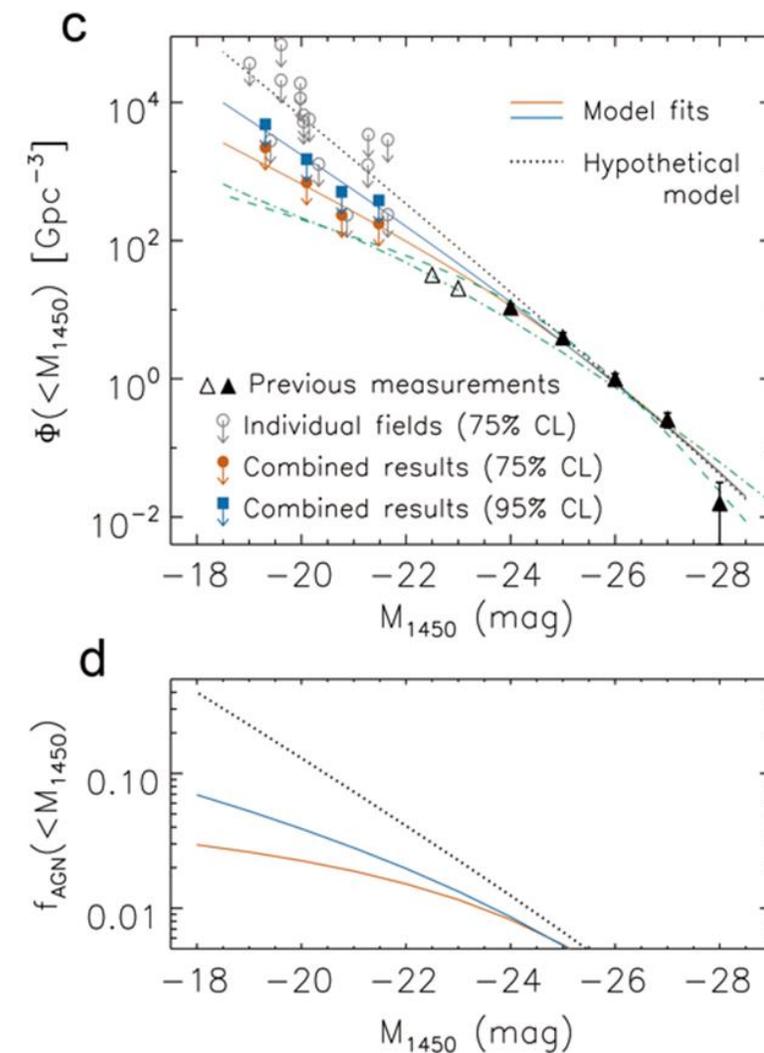

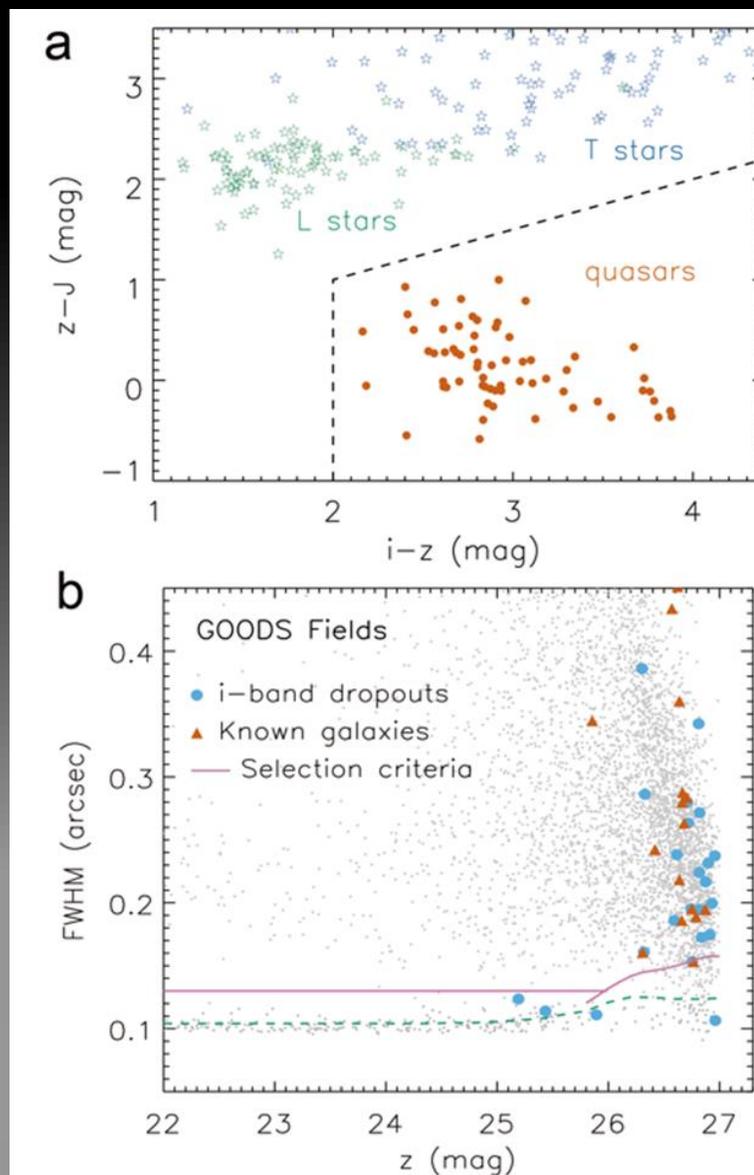

Optical depth of free electron:

$$\tau_e = \int_0^{\infty} dz \frac{c(1+z)^2}{H(z)} Q_{\text{HII}}(z) \sigma_T \bar{n}_H (1 + \eta Y/4X),$$

AGNs are not likely the dominant sources for EoR

- **Before the launch of JWST:** Quasar could not dominate the budget (<7% at $z > 6$, Jiang et al. 2022; 1% at $z > 7$, Matsuoka et al. 2023)
- **After the launch of JWST:** Although an unexpectedly large number of AGNs were identified (i.e., “Little Red Dots”), they still play a minimal role in dominating the ionizing budget (e.g., Dayal et al. 2024, Jiang et al. 2025).

Jiang et al. 2022, Nat. Ast.

Sources responsible for reionization

The current view: SFGs dominate the budget of ionizing photons required by the EoR
(e.g., Robertson et al. 2013, 2015)

The amount of ionizing photons from SFGs: $n_{ion} = f_{esc} \times \xi_{ion} \times \rho_{UV}$

ρ_{UV} UV luminosity density, obtained by intergrating UV LF (Oesch et al. 2018, Bowler et al. 2020, Bouwens et al. 2021a, Harikane et al. 2022)

ξ_{ion} Ionizing Photons Production Efficiency, obatined by observations of nebular lines (Bouwens et al. 2016, Lam et al. 2019, De Barros et al. 2019)

f_{esc} Escape Fraction of LyC Photons -> How many ionizing photons could escape from galaxies?

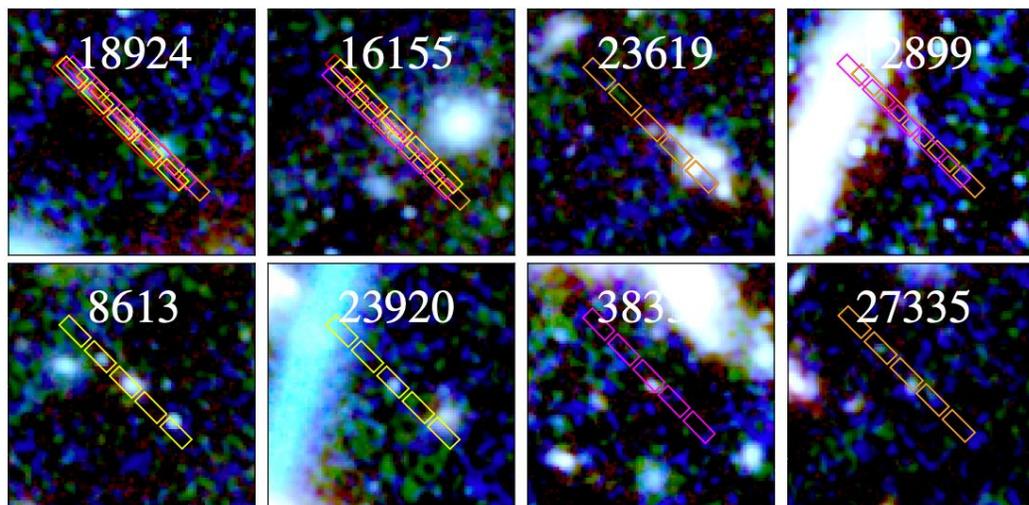

Currently, the uncertainty of the budget is dominated by f_{esc}

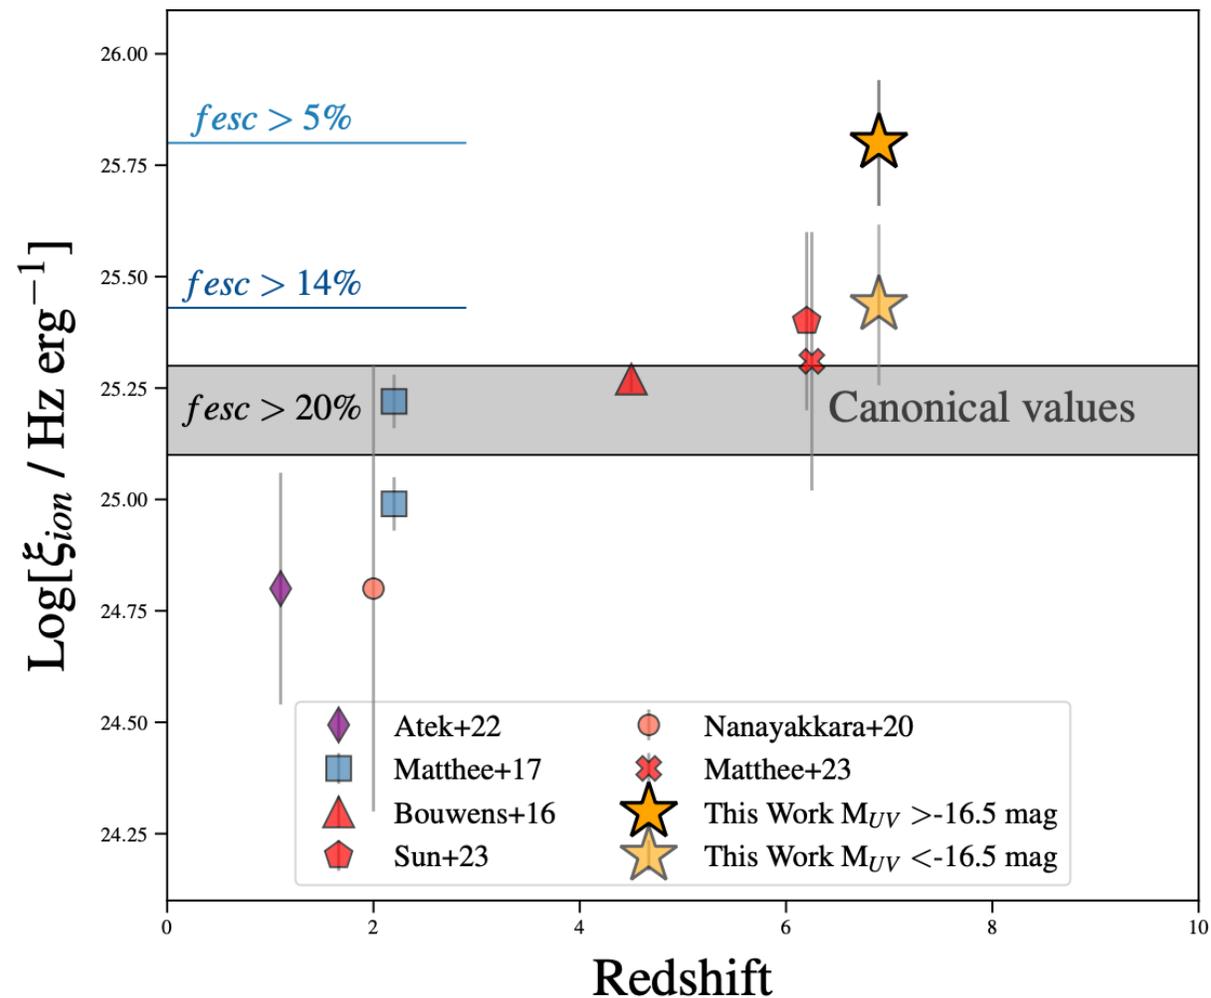

Requirements on f_{esc}

Previous studies claim that an average fraction of 20% or a comparable value is required to satisfy the boundary condition measured by probes of the EoR (e.g., Robertson et al. 2013, 2015)

Recent JWST observations found that the ξ_{ion} for faint galaxies is higher than the canonical values, thus loosening the requirements on f_{esc} .

$$n_{ion} = f_{esc} \times \xi_{ion} \times \rho_{UV}$$

e.g, Atek et al. 2024

The Generation and Escape of LyC Photons

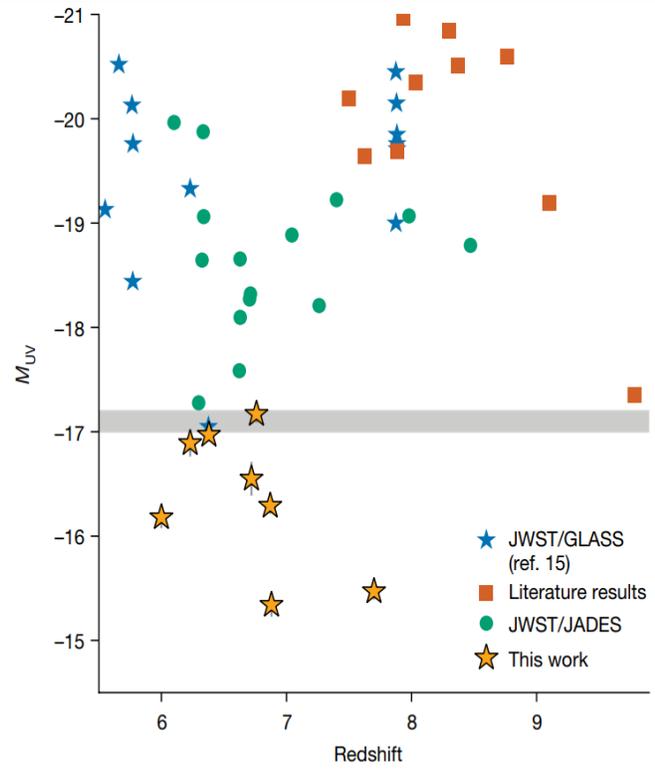

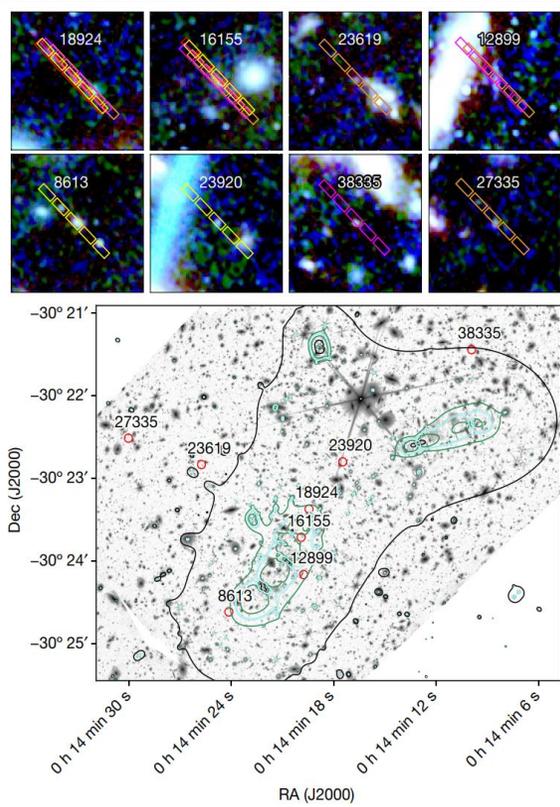

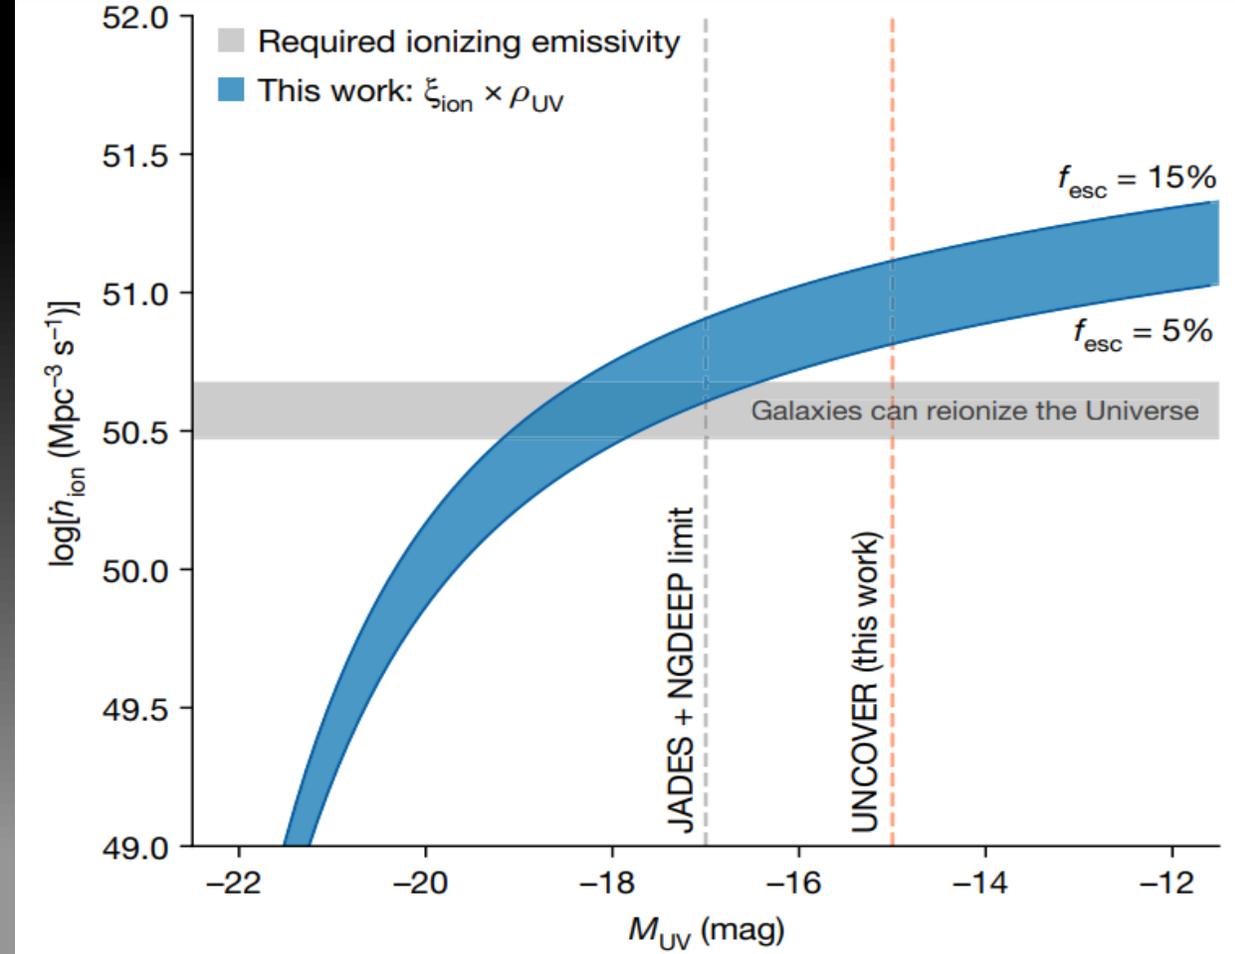

Fig. 2 | Spectroscopic observations of the faintest galaxies during the epoch of reionization. Various literature results from ground-based, HST and

Atek et al. 2024, Nature

- Reionization is Dominated by SFGs rather than AGNs in the EoR (Jiang et al. 2022, Atek et al. 2024, Jiang et al. 2025). But **JWST's Little Red Dots** may bring in sth. new (e.g., Matthee et al. 2023; Madau+2024)

The Generation and Escape of LyC Photons

Measuring f_{esc} from analogs of galaxies in the EOR

- **Low- z starburst system:** The low mass compact galaxies with active star formation are good candidates (Izotov, Guseva & Thuan 2011, Jaskot & Oey 2013) and many positive detection are reported (e.g., Borthakur et al. 2014, Izotov et al. 2018a, 2018b, Flury et al. 2018).
- Galaxies at **$3 < z < 4$** : LAEs/LBGs at $3 < z < 4$ and some LyC leakers and candidates are reported (Vanzella et al. 2012, 2015, 2018, Yuan et al. 2021, Wang et al. 2023, Liu et al. 2023).
- **However**, the difficulty is the identification (faintness, contamination by lower redshift interlopers, and attenuation by partially neutral intergalactic medium).
- Galaxies at **$z > 5$** : **Impossible** to detect their LyC signals due to the IGM absorption.

A Systematic Study of LyC Leaking Galaxies at $3 < z < 4.5$

Average fesc is low

- Most galaxies are non-detections in the LyC regime, and the average fesc is low ($< 10\%$)
 - Wang et al. 2024: fesc $< 6\%$ for ~ 80 non-detections at $2.4 < z < 3.7$, Rutkowski et al. 2016 fesc $\sim 2.1\% - 9.5\%$ at $z \sim 1$.

Some galaxies exhibit high fesc values (LyC leakers, at $3 < z < 4$)

- GOODS-S: Saxena et al. 2022, Rivera-Thorsen et al. 2022, Vanzella et al. 2012; Ji et al. 2020 (*Ion1*), Vanzella et al. 2015, 2016 (*Ion2*), Yuan et al. 2021 (CDF5-6664)

Systematic offsets in properties of different studies

Using the same method and data

Inaccurate SED models (missing nebular emission models)

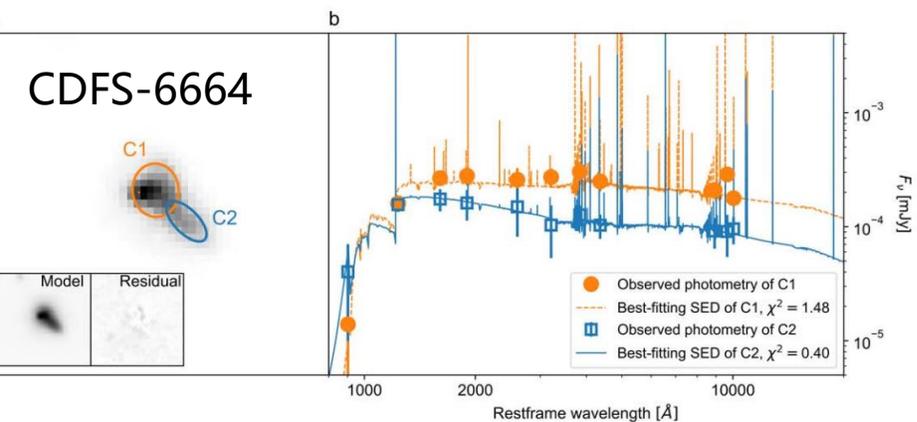

Improving by sophisticated SED models

Inaccurate photometric data at $\lambda > 2.5 - 3 \mu\text{m}$

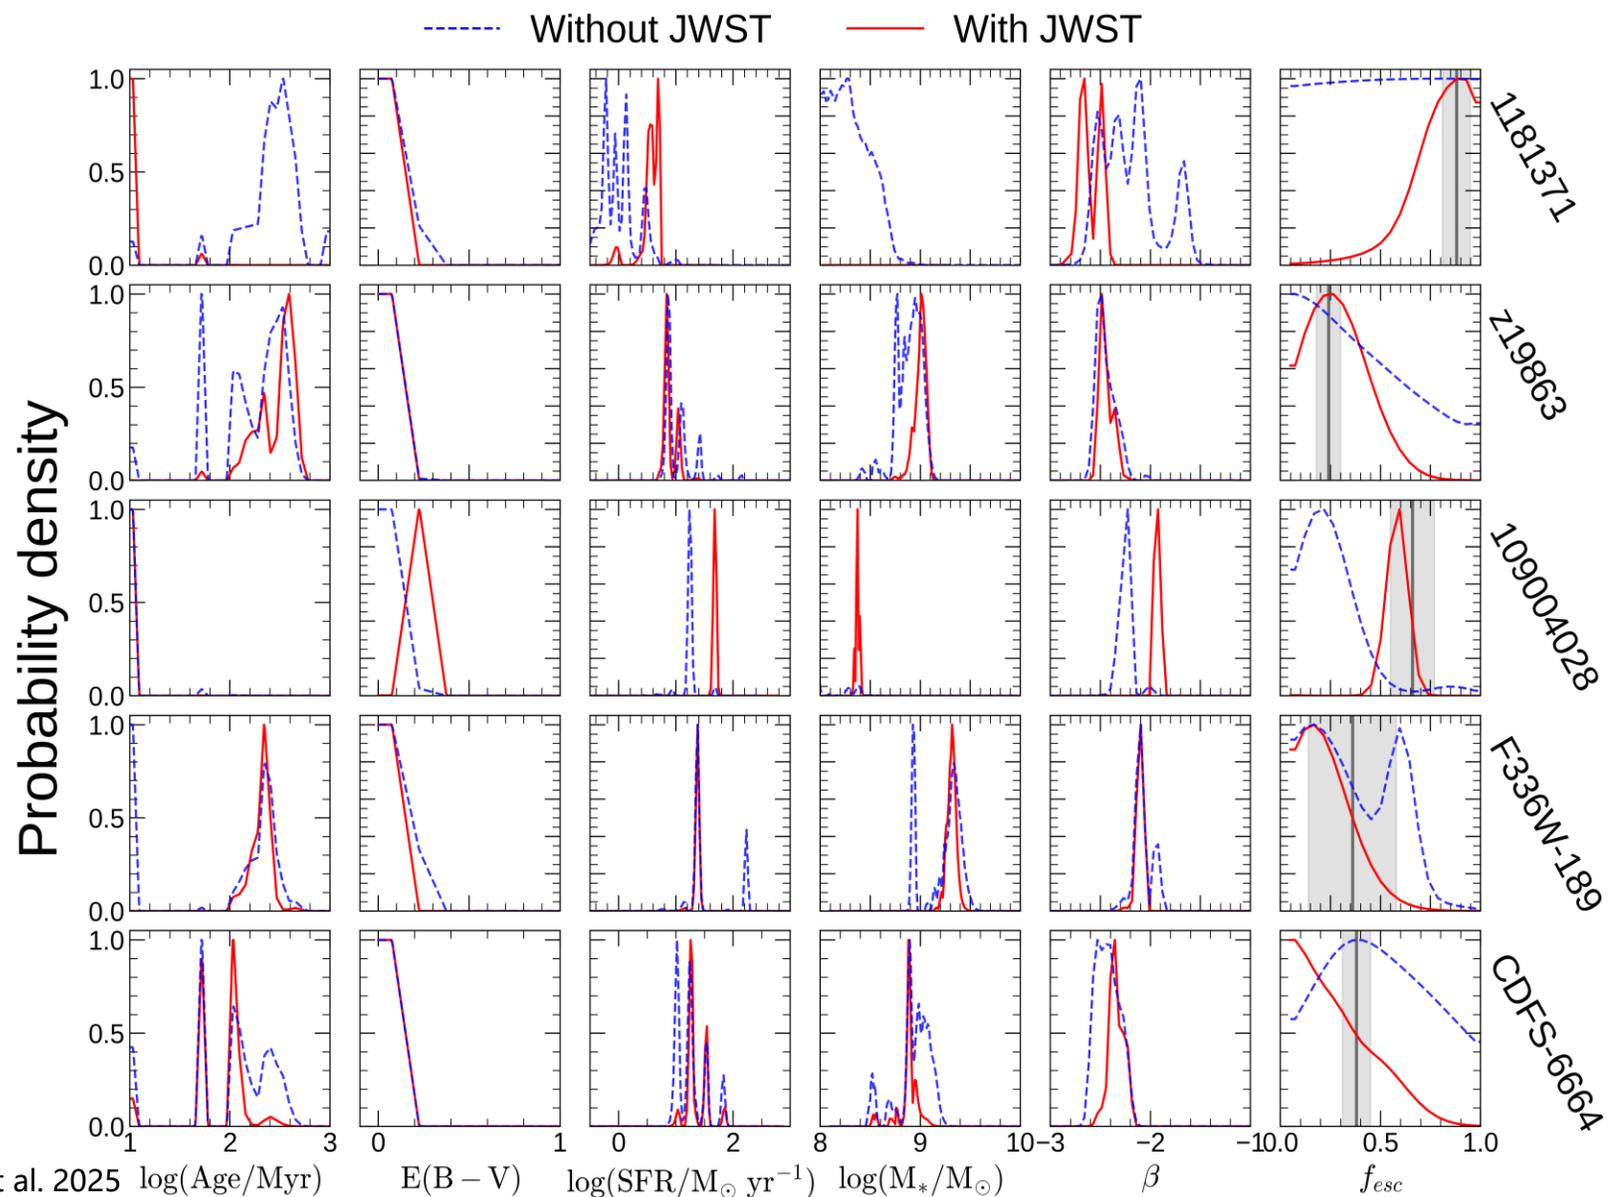

Improving by using JWST data

Result 1: The SED of LyC Leakers-I

JWST helps constrain properties better

- Narrow the distributions of probability densities
- Break the degeneracy in properties

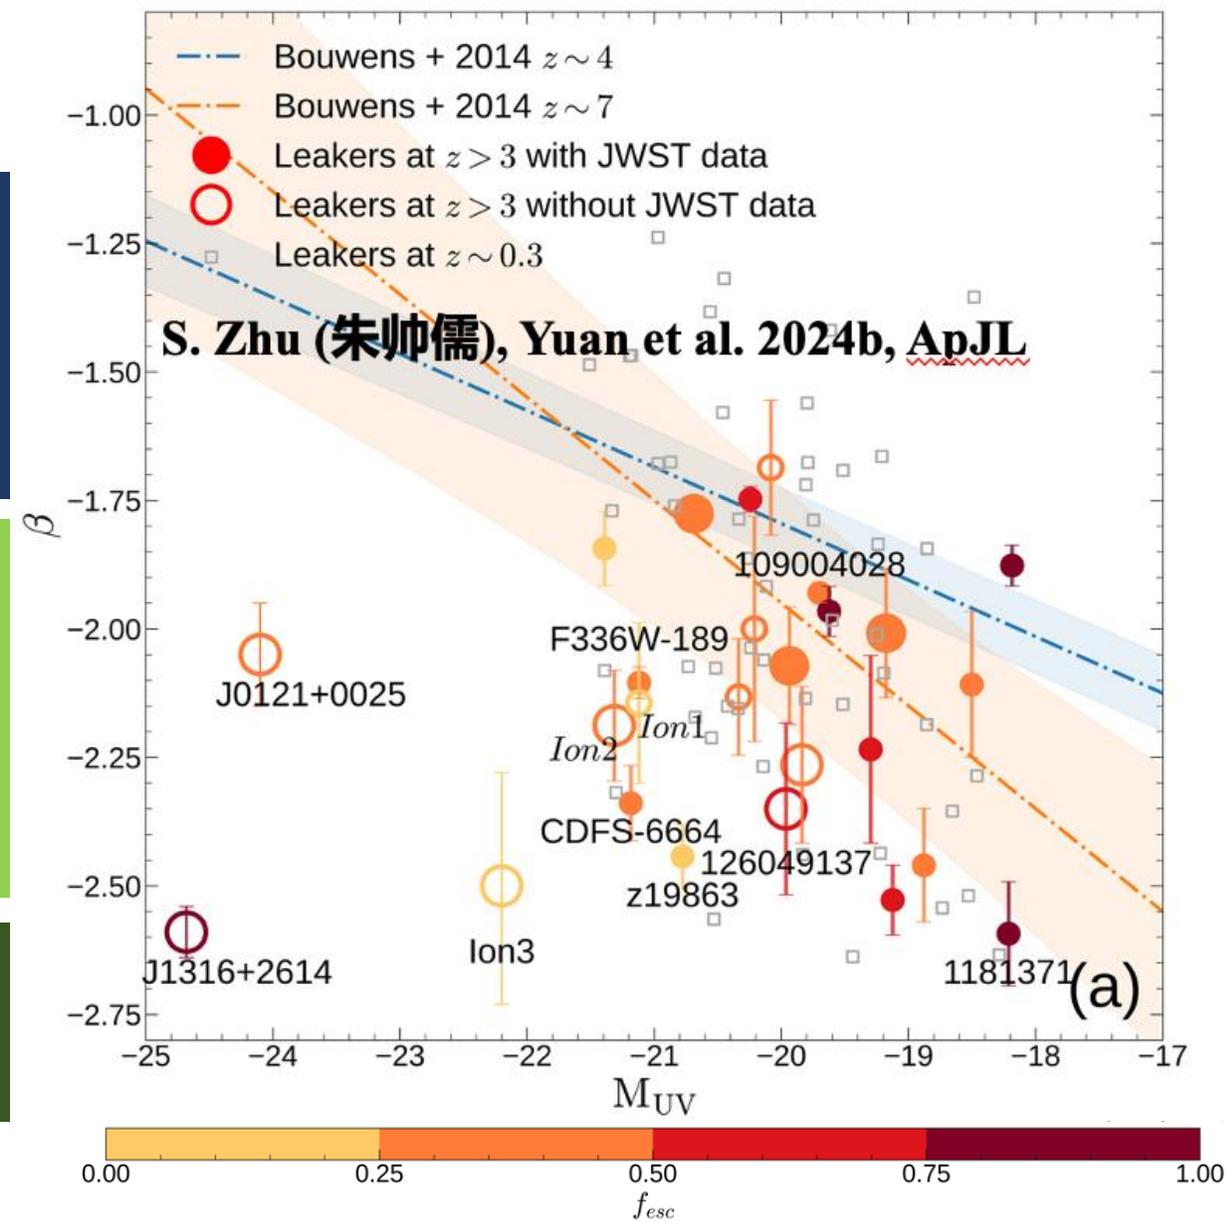

Result 1: The SED of LyC Leakers-I

The UV property I

Low-z leakers: They are consistent with the β - M_{UV} relation at $z \sim 7$, also a f_{esc} - β correlation is reported (Chisholm et al. 2022)

High-z leakers: Most LyC leakers align with $z \sim 7$ the β - M_{UV} relation and some overlap with $z \sim 8$ galaxies in the β - M_{UV} diagram.

Comparison: High-z leakers are bluer than those at low-z

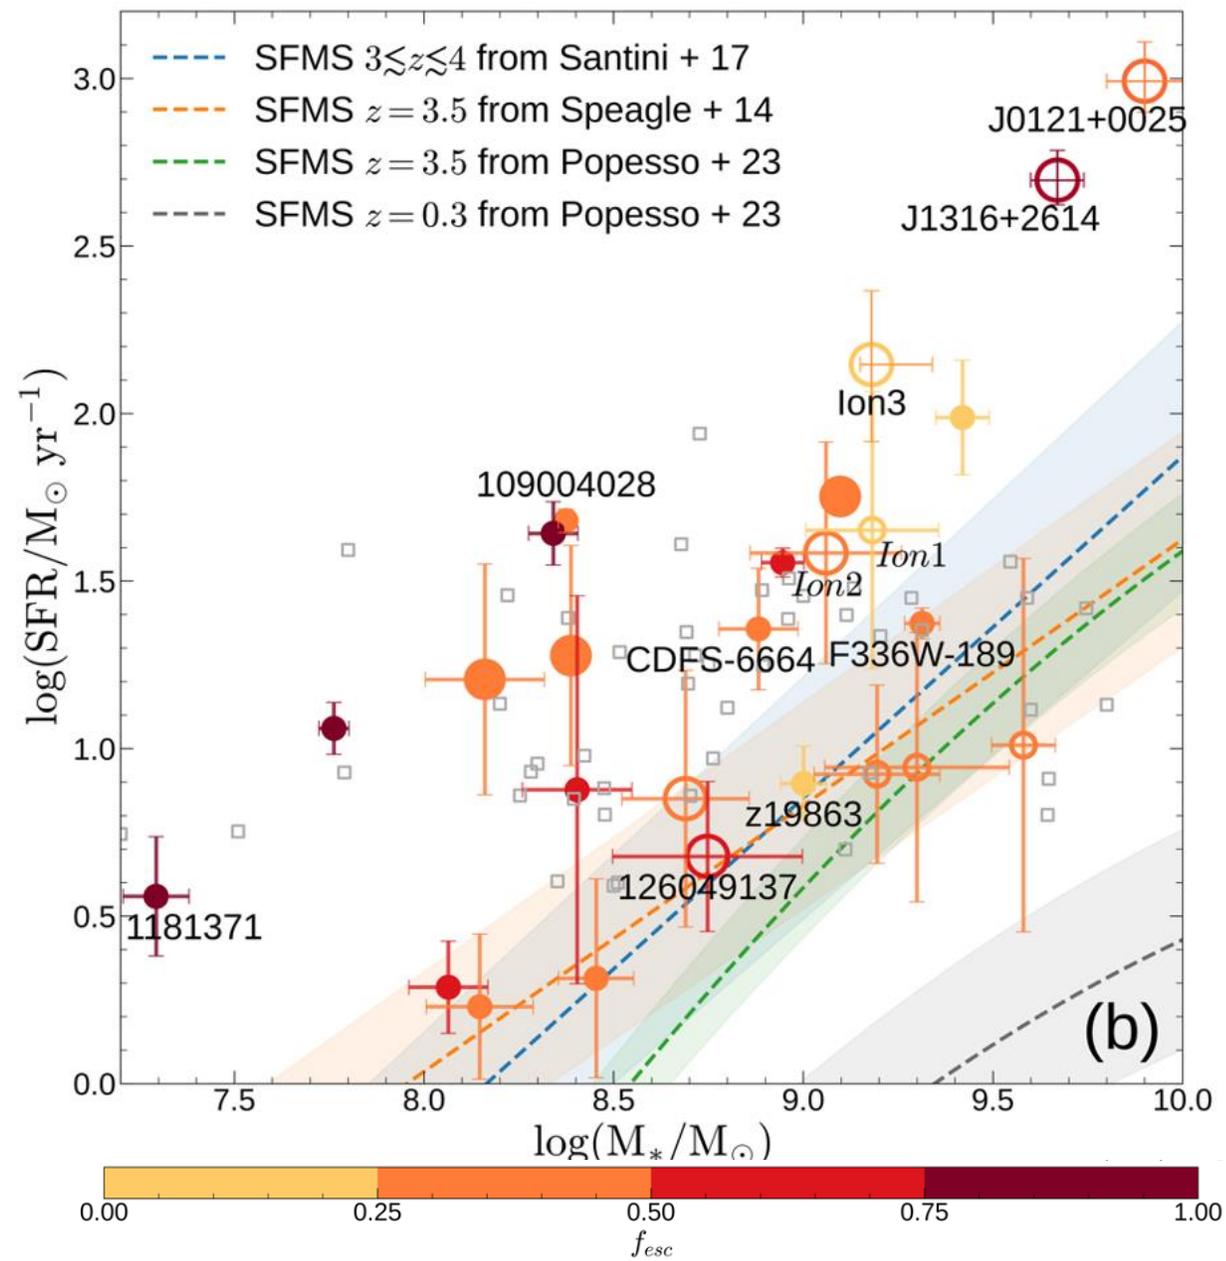

Result 1: The SED of LyC Leakers-II

The star formation property I

Low-z leakers: All leakers are in the starburst region.

High-z leakers: Some high-z LyC leakers are not starburst systems, although some leakers are undergoing intense star formation.

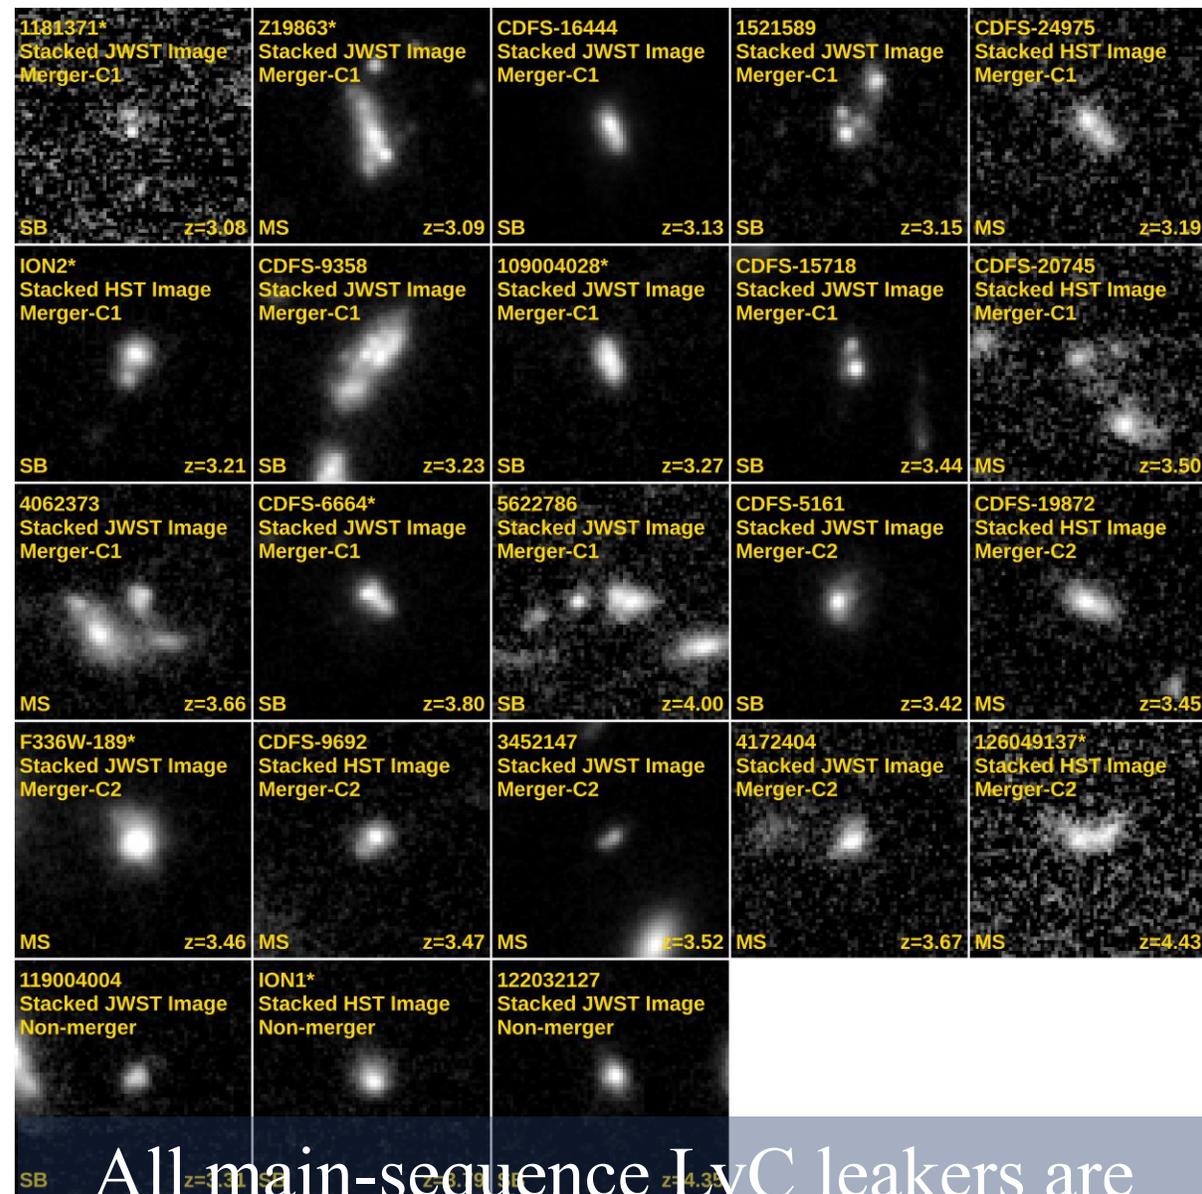

Comparison: High-z and low-z leakers fall in a similar region in this diagram.

Result 2: The Morphology of LyC Leaker-I

Visual inspection (High-z)

- **Methods:** Two types of galaxy mergers are identified in this work: (1) galaxies with two or more cores and/or close companions and (2) galaxies that exhibit extended, elongated structures or long tails.
- **Results:** 20/23 for high-z
- **Comparison:**
 - ~ 40% - 50% for brightest galaxies at $z \sim 2-3$; ~56% for high-z LAE & LBG sample (See Jiang et al. 2012 and reference therein)
 - Witten et al. 2024 : **100%** of LAEs in their sample at $z > 7$ have close companions

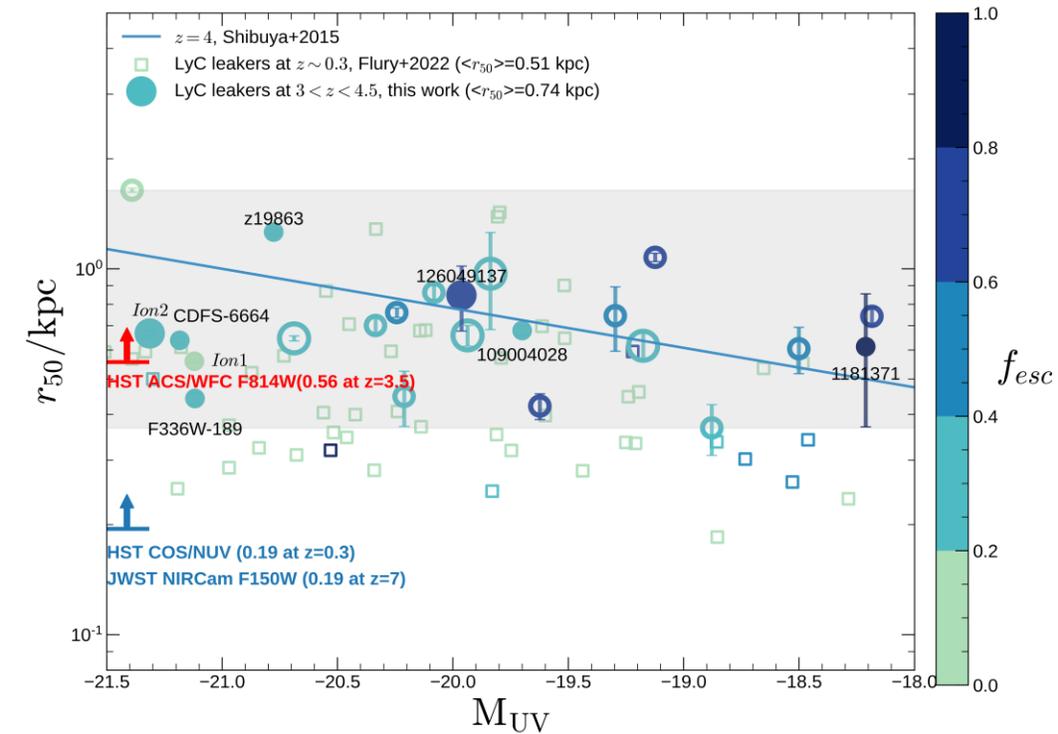

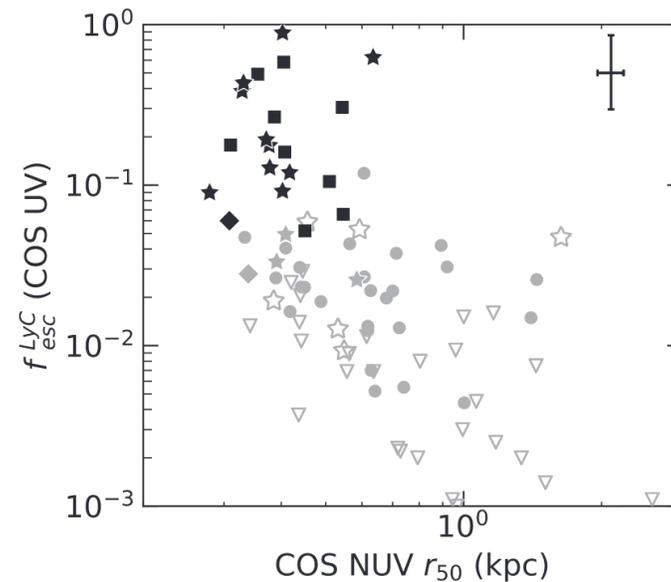

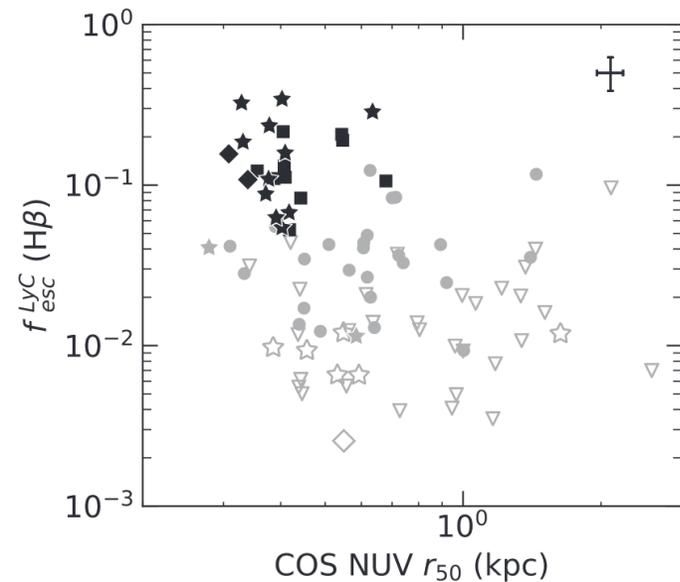

All main-sequence LyC leakers are mergers

Result 2: The Morphology of LyC Leaker-II

Sizes versus f_{esc}

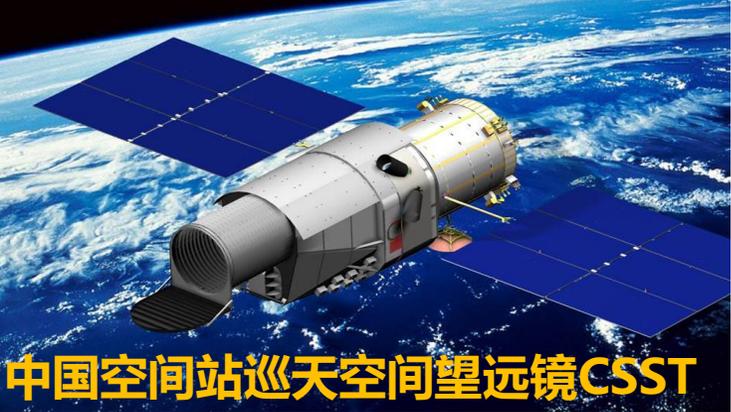

- **At low- z :** A clear trend between f_{esc} and UV sizes is found based on the LzLCS+ sample, however massive leakers exhibit extended structures
- **At high- z :** No such trend is found based on our sample

Summary on Our Systematic Study of LyC Galaxies at $3 < z < 4.5$

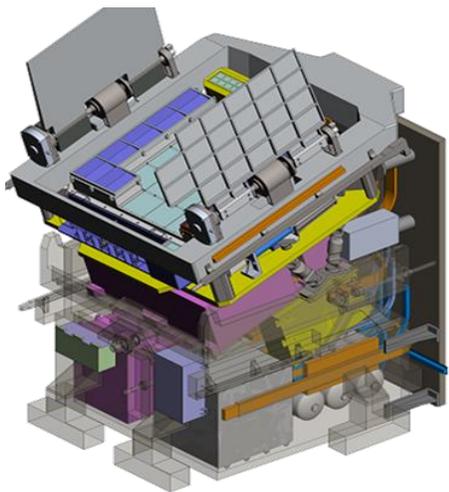

- We conduct a systematic analysis of the physical properties and morphologies of LyC leakers at $3 < z < 4.5$ and compared them to those at $z \sim 0.3$:
 - **UV properties:** The high- z leakers exhibit more blue UV color compared to low- z leakers;
 - **Star formation:** Unlike low- z leakers, our results show intense bursts of star formation are not necessarily required for the leakage of LyC photons for galaxies at $z > 3$. They also exhibit lower Σ_{SFR} but Σ_{SFR} are similar in the comparable size range;
 - **Morphology:** All main-sequence leakers are mergers and almost all leakers are mergers, suggesting merging activity could also facilitate the LyC photon escaping;
 - **Sizes:** High- z leakers in the GOODS-S tend to be more extended, compared to the galaxies at $z > 5$ and low- z leakers.

What's next? More deep UV surveys are needed!
